\mathcal{F}	The data manifold. \mathcal{F} is a parameterizable d -manifold in \mathbb{R}^m , with $d < m$.
d	The underlying dimension of the data manifold \mathcal{F} , i.e., the “feature” space.
m	The dimension of the higher dimensional “input” space.
f	$f : C \subset \mathbb{R}^d \rightarrow \mathbb{R}^m$ is a smooth map which parameterizes \mathcal{F} .
C	$C \subset \mathbb{R}^d$ is a compact subset of \mathbb{R}^d .
x_i	$x_1, \dots, x_N \in \mathbb{R}^m$ are the data points in the higher dimensional space.
τ_i	$\tau_1, \dots, \tau_N \in \mathbb{R}^d$ are the corresponding feature space coordinates of the x_i 's, where $x_i = f(\tau_i) + \epsilon_i$.
ϵ_i	$\epsilon_1, \dots, \epsilon_N \in \mathbb{R}^d$ is the added noise to $f(\tau_i)$ to obtain x_i .
X	$X = \begin{bmatrix} & & \\ x_1 & \cdots & x_N \\ & & \end{bmatrix}$ is the matrix form of the data.
J_f	$J_f(\tau) = \begin{bmatrix} \partial f_1 / \partial \tau_1 & \cdots & \partial f_1 / \partial \tau_d \\ \vdots & \ddots & \vdots \\ \partial f_m / \partial \tau_1 & \cdots & \partial f_m / \partial \tau_d \end{bmatrix}$ is the Jacobi matrix of f at τ .
$\bar{\tau}$	$\bar{\tau}$ is some point near τ used for the following approximation via Taylor expansion: $f(\bar{\tau}) = f(\tau) + J_f(\tau) \cdot (\bar{\tau} - \tau) + O(\ \bar{\tau} - \tau\ ^2)$.
\mathcal{T}_τ	$\mathcal{T}_\tau = \text{span}(J_f(\tau))$ is the tangent space of f at τ .
Q_τ	Q_τ is a matrix forming some orthonormal basis of \mathcal{T}_τ , allowing us to write $J_f(\tau)(\bar{\tau} - \tau) = Q_\tau \theta_\tau^*$.
θ_τ^*	??? Possibly defined by $Q_\tau \theta_\tau^* = f(\bar{\tau}) - f(\tau)$?
P_τ	Defined by $\theta_\tau^* = Q_\tau^T J_f(\tau)(\bar{\tau} - \tau) \equiv P_\tau(\bar{\tau} - \tau)$.
θ_τ	The mapping from τ to θ_τ^* is a local affine transformation. θ_τ is the orthogonal projection of $f(\bar{\tau}) - f(\tau)$ onto \mathcal{T}_τ . $\theta_\tau \equiv Q_\tau^T(f(\bar{\tau}) - f(\tau)) = \theta_\tau^* + O(\ \bar{\tau} - \tau\ ^2) \approx \theta_\tau^*$.
$\Omega(\tau)$	$\Omega(\tau)$ defines the neighborhood of τ .
X_i	$X_i = \begin{bmatrix} & & \\ x_{i_1} & \cdots & x_{i_k} \\ & & \end{bmatrix}$ is a matrix consisting of the k -nearest neighbors of x_i .
x	x is part of the minimization problem $\min_{x, \Theta, Q} \sum_{j=1}^k \ x_{i_j} - (x + Q\theta_j)\ _2^2 = \min_{x, \Theta, Q} \ X_i - (xe^T + Q\Theta)\ _2^2.$ The optimal x is \bar{x}_i – the mean of all the x_{i_j} 's.
Q	Q is another term in the minimization (but what is it???). It is of d columns. Optimal Q is given by the d singular vectors of $X_i(I - ee^T/k)$ corresponding with the d largest singular values.
Θ	$\Theta = \begin{bmatrix} & & \\ \theta_1 & \cdots & \theta_k \\ & & \end{bmatrix}$ is a matrix consisting of the orthogonal projections of each $x_{i_j} - x$ onto \mathcal{T}_{x_i} . Θ is given by $\Theta_i = Q_i^T X_i(I - \frac{1}{k}ee^T) = \begin{bmatrix} & & \\ \theta_1^{(i)} & \cdots & \theta_k^{(i)} \\ & & \end{bmatrix}$, $\theta_j^{(i)} = Q_i^T(x_{i_j} - \bar{x}_i)$.
$\xi_j^{(i)}$	$\xi_j^{(i)} = (I - Q_i Q_i^T)(x_{i_j} - \bar{x}_i)$ is the global reconstruction error of x_{i_j} , with $x_{i_j} = \bar{x}_i + Q_i \theta_j^{(i)} + \xi_j^{(i)}$.
τ_{i_j}	τ_{i_j} is the feature space coordinate of x_{i_j} . We want $\tau_{i_j} = \bar{\tau}_i + L_i \theta_j^{(i)} + \epsilon_j^{(i)}$, for $j \in \{1, \dots, k\}$ and $i \in \{1, \dots, N\}$.
$\bar{\tau}_i$	$\bar{\tau}_i$ is the mean of the τ_{i_j} , for $j \in \{1, \dots, k\}$.
L_i	L_i is the local affine transformation for τ_i .
E_i	$E_i = \begin{bmatrix} & & \\ \epsilon_1^{(i)} & \cdots & \epsilon_k^{(i)} \\ & & \end{bmatrix}$ is the matrix form of the local reconstruction error.
e	$e = [1 \cdots 1]^T$ is a column vector of all ones of dimension k .
T_i	$T_i = \begin{bmatrix} & & \\ \tau_i & \cdots & \tau_k \\ & & \end{bmatrix}$ is the matrix form of the feature space coordinates. It satisfies $T_i = \frac{1}{k} T_i e e^T + L_i \Theta_i + E_i$, so $E_i = T_i(I_k - \frac{1}{k} e e^T) - L_i \Theta_i$.
S_i	S_i is the 0-1 selection matrix such that $T S_i = T_i$.
S	$S = [S_1 \cdots S_n]$.
W_i	$W_i = (I_k - \frac{1}{k} e e^T)(I - \Theta_i^+ \Theta_i)$.

W	$W = \text{diag}(W_1, \dots, W_N) = \begin{bmatrix} W_1 & 0 & \dots & 0 \\ 0 & W_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & W_N \end{bmatrix}.$
T	<p>We want to find T to minimize the overall reconstruction error $\sum_i \ E_i\ _F^2 = \ TSW\ _F^2$.</p> <p>To determine T, we require $TT^T = I_d$.</p>
B	<p>$B \equiv SWW^T S^T$ has eigenvector e corresponding to eigenvalue 0. Thus, optimal T is given by the d eigenvectors corresponding to the 2nd to $d + 1$st smallest eigenvalues.</p>
